PLANKTON STUDIES IN SAN FRANCISCO BAY, IX.

CHLOROPHYLL DISTRIBUTIONS AND HYDROGRAPHIC PROPERTIES

OF SOUTH SAN FRANCISCO BAY, 1984 - 1986

---

By Andrea E. Alpine, Sally M. Wienke, James E. Cloern, and Brian E. Cole

ABSTRACT

This report summarizes the distribution of phytoplankton biomass and selected hydrographic properties in South San Francisco Bay during 1984-1986. There were a total of 67 cruises during the three-year period with the most frequent sampling occurring during the spring. Parameters measured were chlorophyll a, phaeopigments, in-vivo fluorescence, turbidity, salinity, and temperature.

## INTRODUCTION

Data are presented to summarize results of surveys of water quality in South San Francisco Bay (SSFB) during 1984 - 86. Measurements of salinity, temperature, turbidity (nephelometry), and in-vivo fluorescence were made in near-surface waters of the main shipping channel of the South San Francisco Bay. At some stations these same parameters were measured at 3-6 depths of the water column. Chlorophyll *a*, phaeopigments, and light attenuation (measured with a Secchi disk) also were measured at these stations. Discrete measurements of salinity were made at some locations to calibrate the continuous flow system. Locations of sampling stations are given in Table 1.

## METHODS

### Sampling System

Sampling sites are shown in Figure 1 and identified in Table 1 by the universal transverse mercator (UTM) system (shortened to include only digits significant to SSFB). Station positions were determined ( $\pm 0.2$  km) using radar.

The stations (Table 1) were sampled from the R/V POLARIS using one of two sampling modes, surface (i.e., longitudinal) profiling and vertical profiling. In the surface profiling mode water was pumped from a through-the-hull fitting located near the bow of the vessel at a depth of approximately one meter. For vertical profiling a submersible pump was lowered to obtain samples from specific depths.

The pumped sample was directed through various instruments (see below) for continuous analyses: salinity, temperature, in-vivo fluorescence and turbidity (nephelometry). At selected stations, discrete samples were

collected from the pumped water as it exited the continuous instrumentation. The discrete samples were taken for measurement of chlorophyll *a* and phaeopigments, and for salinity. Light attenuation was determined while at anchor.

The following descriptions of the separate analyses are divided into two sections: continuous analyses and discrete analyses.

#### Continuous Analysis

Salinity was measured continuously with a flow-sample electrodeless induction salinometer (Schemel and Dedini, 1979). For calibration, 3 to 14 discrete samples (DISCR SALIN) were collected over the encountered salinity range during each cruise and analyzed with a high-precision ( $\pm 0.003$  ppt) Beckman<sup>R</sup> salinometer<sup>1</sup> calibrated with Copenhagen water. The reported salinities (SALIN) were calculated from linear regression of the discrete samples against the continuous readings.

Temperature (TEMP) was measured by probes inserted into the sample stream (Schemel and Dedini, 1979). The probes are linearized thermistor elements, calibrated at ice point and near 20° C. Temperature measurements are accurate within  $\pm 0.2^{\circ}$  C.

In-vivo fluorescence (FLUOR) was measured continuously with a Turner Designs<sup>R</sup> Model 10 fluorometer. Linear regressions of measured chlorophyll *a* (DISCR CHL A) against in-vivo fluorescence were used to determine a calculated chlorophyll *a* (CALC CHL A) for each fluorescence reading (CALC CHL A =  $a_1 + b_1 * \text{fluorescence}$ ). Samples taken from station 33 were

---

<sup>1</sup> The use of brand names is for identification purposes only and does not constitute endorsement by the U.S. Geological Survey.

not used in the regressions because this area often has very high levels of phaeopigments, and species may occur in the phytoplankton population of this area that do not occur in the rest of SSFB. Regression and correlation coefficients presented at the bottom of each data summary show how well (or poorly) these parameters correlate. Caution should be exercised in using calculated chlorophyll *a* values when the coefficient of determination ( $r^2$ ) is less than 0.70. Also note that some of these regressions produce negative intercepts (i.e., there is fluorescence in the water not associated with particulate chlorophyll *a*).

A Secchi disk was used to measure the attenuation of light. The extinction coefficient (EXCOF) was calculated from the equation  $e = 0.4 + 109/SD$  (where SD is the Secchi depth in centimeters). The equation was derived from studies in 1980 (unpublished data) when Secchi depth and light extinction (measured with a quantum sensor) were simultaneously measured.

Turbidity was continuously measured with a Turner Designs<sup>R</sup> Model 10 fluorometer equipped with a 10-033 nephelometry attachment (Schemel and Dedini, 1979). Regressions of extinction coefficient against nephelometer value for each sampling station were used to calculate extinction coefficients (CALC EXCOF) from continuous nephelometer output (CALC EXCOF =  $a_2 + b_2 * \text{nephelometer value}$ ). Again, caution should be exercised when using calculated values where the coefficient of determination is less than 0.70.

#### Discrete Analyses

Samples for chlorophyll *a* (DISC CHL A) and phaeopigments (DISCR PHAE0) were collected from the pumped sample stream as it exited from the fluorometer. The sample was filtered at less than 5 psi through a Gelman<sup>R</sup> glass fiber filter and immediately frozen. The filter then was ground in

90 percent acetone with a teflon tissue grinder. After extraction for 12-24 hours in a refrigerator, samples were centrifuged and absorbances read on a Varian<sup>R</sup> 635D spectrophotometer. Samples were acidified (Riemann, 1979) to measure phaeopigments. Chlorophyll a and phaeopigment values were calculated using Lorenzen's (1967) equations.

Chlorophyll a concentration divided by chlorophyll a concentration plus phaeopigment concentrations (CHL a/a + PHA) is an estimate of the proportion of chlorophyll a to chlorophyll a plus its degradation products.

Tidal phase (tide) was noted by visual observation and recorded as flood (+1), slack (0), and ebb (-1).

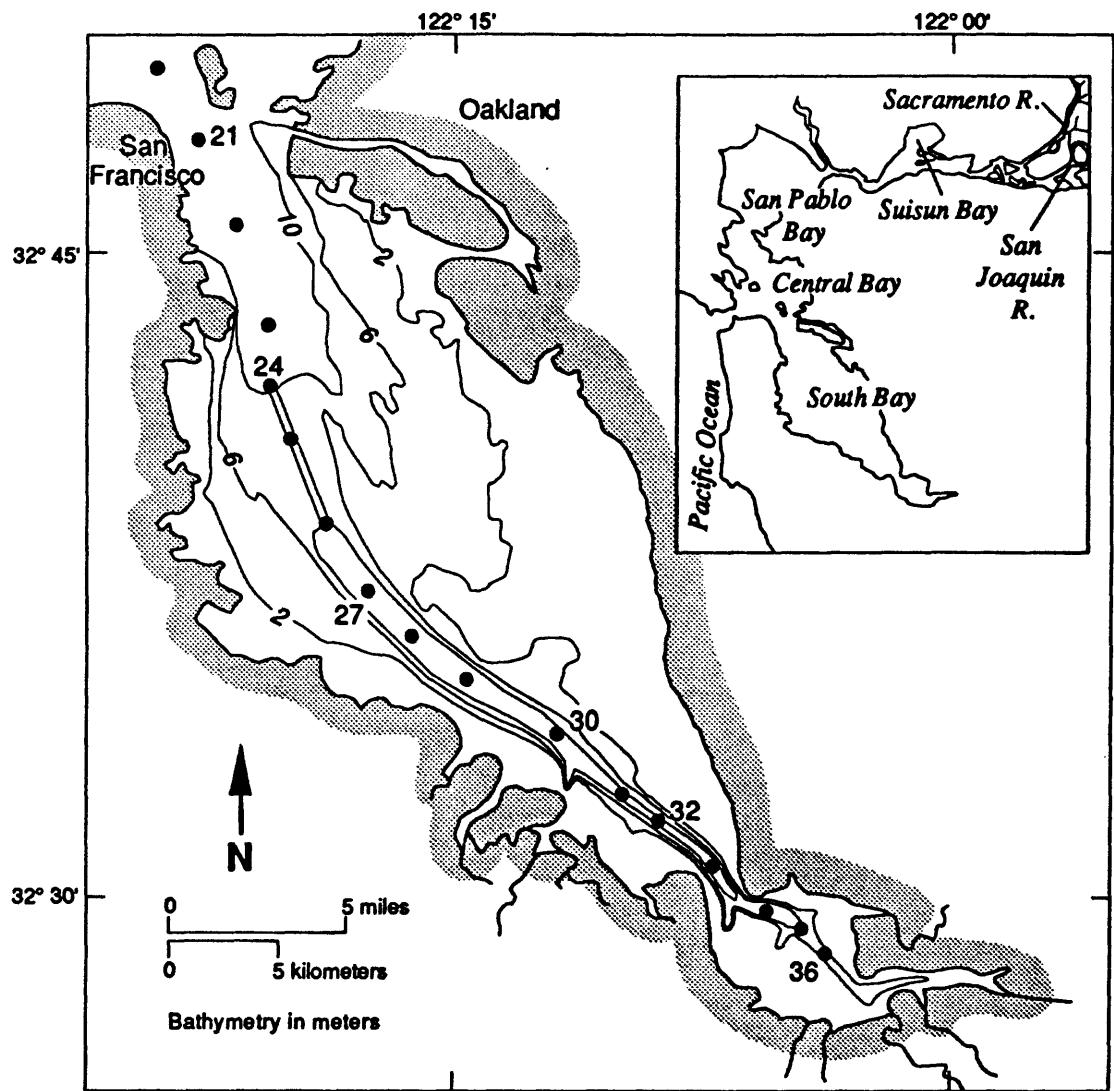

All times (TIME) are local time, either Pacific Daylight or Pacific Standard Time.
